Use Case Summary	A brief summary describing the overall purpose and functionality of the use case.	UC 4.1 aims to streamline hotel check-in and pre-registration processes using the European Digital Identity Wallet (EUDIW). Guests like Maria can use their EUDIW to share necessary identity attributes with the hotel before arrival, enabling a seamless and queue-free check-in experience upon arrival, without the need for physical documents or manual data entry.
UC User Story	A user-facing description of the use case focusing on who, what, and why.	As a hotel guest, I want to pre-register for my stay using my EUDIW on my phone, so that I can bypass the check-in desk and get my key without any delay when I arrive.
Actors (referecing Partners from Partners list)	The entities or roles that interact with the system or are involved in the use case.	**User:** A traveler (e.g., Maria from Spain). **Relying Party (RP):** A hotel (e.g., in Paris, France). **PID Issuer:** The Spanish Government. **Credential Issuer (CI):** The hotel or its booking platform (for the Booking Confirmation EAA).
Context & Pre-conditions	Business and environmental factors and conditions that must be true or in place before the use case can begin.	Maria has an EUDIW issued by Spain on her smartphone, containing her verified PID. The hotel in Paris is a participant in the APTITUDE pilot and its system is integrated with the EUDIW framework. Maria has made a booking at the hotel.
Credentials Involved	The specific credentials or attestations necessary for the use case to function.	**PID (Personal Identification Data):** To verify name, age, and nationality as required by local regulations. **Booking Confirmation EAA:** Issued by the hotel/booking platform to link her wallet to a specific reservation.
User Journey (Business flow of events)	A chronological sequence of interactions a user has with a system (Wallet providers, PID providers, services, etc.) to perform the business goal.	**1. Booking:** Maria books a room at the Parisian hotel through its website. **2. Pre-Arrival:** A day before her trip, Maria receives an email from the hotel inviting her to “pre-check-in.” **3. Data Sharing:** Maria clicks the link, prompting her EUDIW to open. She reviews the request (name, nationality, DOB) and consents to share this data. **4. Arrival:** On arrival, Maria bypasses the queue, scans a QR code at a kiosk/desk, and her identity is instantly confirmed. No physical passport needed.
Technical Flow	The sequence of technical interactions and system input/output underlying the user journey. Include respective flow diagrams that depict actors, processes, etc.	1. The hotel’s system (RP) initiates an identity verification request. 2. Maria’s EUDIW receives the request and displays the specific attributes requested (selective disclosure). 3. Maria authenticates to her wallet (e.g., biometrics) and approves sharing. 4. The EUDIW creates a verifiable presentation containing the signed PID attributes and sends it to the hotel’s backend. 5. The hotel system validates the signature/integrity against the trusted issuer list. 6. The system matches the identity with the booking and flags Maria as “checked-in.”
Unhappy paths	Alternative flows and exceptions that deviate from the happy path/flow. Possible exceptions, edge cases.	Unhappy path 1: Unverified credentials Unhappy path 2: Unverified signature …
